IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Attorney Docket No.:	**DEX-0087**
Inventors:	**Recipon et al.**
Serial No.	**09/705,500**
Filing Date:	**November 3, 2000**
Examiner:	**Canella, Karen A.**
Group Art Unit:	**1642**
Title:	**A Novel Method of Diagnosing, Monitoring, Staging, Imaging and Treating Cancer**

Declaration under Rule § 1.131

We, Herve Recipon, Roberto A. Macina, Sei-Yu Chen and Yongming Sun, hereby declare:

1. We are co-inventors of the above-referenced patent application.

2. As the co-inventors of the above-referenced patent application, we are familiar with the teachings of the above-referenced patent application.

3. The use of Lng108, also known as fy108, as a cancer diagnostic was conceived and reduced to practice in this country at diaDexus, Inc., prior to October 27, 1999 which was located at that time in Santa Clara, California, USA.

4. Specifically, Lng108 relative expression was determined in accordance with our standard Quantitative Polymerase Chain Reaction (QPCR) protocol and outlined in the above-referenced patent application at page 20, line 16 through page 21, line 13; and page 17, line 12 through page 18, line 9 of priority application U.S. Provisional No. 60/163,144, filed on November 4, 1999. These experiments measuring relative levels of Lng108 in cancerous, normal-adjacent, and normal tissues using Polymerase Chain Reaction in real time were performed prior to October 27, 1999.

Real-Time quantitative PCR with fluorescent Taqman probes is a quantitation detection system utilizing the 5'-3' nuclease activity of Taq DNA polymerase. The method uses an internal fluorescent oligonucleotide probe (Taqman) labeled with a 5' reporter dye and a downstream, 3' quencher dye. During PCR, the 5'-3' nuclease activity of Taq DNA polymerase releases the reporter, whose fluorescence can then be detected by the laser detector of the Model 7700 Sequence Detection System (PE Applied Biosystems, Foster City, CA, USA).

Amplification of an endogenous control was used to standardize the amount of sample RNA added to the reaction and normalize the Reverse Transcriptase (RT) efficiency. Either cyclophilin, glyceraldehyde-3-phosphate dehydrogenase (GADPH) or 18S ribosomal RNA (rRNA) was used as this endogenous control. To calculate relative quantitation between all samples studied, the target RNA levels for one sample were used as the basis for comparative results (calibrator). Quantitation relative to the calibrator can be obtained using the standard curve method or the comparative method (User Bulletin #2: ABI PRISM 7700 Sequence Detection System).

The tissue distribution, and the level of the target gene for every example in normal and cancer tissue were determined. Total RNA was extracted from normal tissues, cancer tissues, and from cancers and the corresponding matched adjacent tissues. Subsequently, first strand cDNA was prepared with reverse transcriptase and the polymerase chain reaction was done using primers and Taqman probe specific to each target gene. The results are analyzed using the ABI PRISM 7700 Sequence Detector. The absolute numbers are relative levels of expression of the target gene in a particular tissue compared to the calibrator tissue.

5. Attached are copies of laboratory notebook pages 0034-124, 0034-168 and 0049-048 containing QPCR experimental procedures and results fro Lng108, also known as fy108. The actual dates upon which these experiments were performed in this country at diaDexus, Inc., prior to October 27, 1999 which was located at that time in Santa Clara, California, USA, have been redacted from the attached copies. These experiments, all performed prior to October 27, 1999, demonstrated the use of Lng108 as a diagnostic marker for cancer.
